Abstract

Background: Hernia is the word derived from Greek words "Herons" an offshoot or bulge. It is defined by Sir Astley Cooper (1804) as "protrusion of any viscus or part of the viscus through an abnormal opening in the walls of its containing cavity. The performed choice of anaesthesia for all adult inguinal hernia repair is local, it is safe, simple, effective, and economical, without anaesthetic side effects. Furthermore local anaesthesia administered before the incision produces longer postoperative analgesia because local infiltration, theoretically inhibits build of local nociceptive molecules and therefore, there is better pain control in the postoperative period. Materials and Methods: This was a randomized, prospective comparative clinical study conducted in the Department of Anesthesiology. Age between 30 and 60 years and only male cases, American Society of Anesthesiologists (ASA I and II) cases, weight 40-65 kg, elective surgeries (inguinal hernioplasty) were included. Patient refusal, known allergy, coagulopathy, patient on β blockers, long-term analgesic therapy, drugs which are known to interact with study drugs. Results: The two groups were matched in respect of their demographic characteristics such as age and weight. The baseline clinical variables such as ASA grade, pulse rate (PR), systolic blood pressure (SBP), diastolic blood pressure (DBP), were matched between the two groups (Table 1). The baseline PR, SBP, and DBP were matched and shown in Table 3. The mean PRs between the two groups were not statistically significant ($86.9 \pm 8.9 \approx 84.5 \pm$ 9.3 and P > 0.05). The mean SBPs between the two groups were not statistically significant (121.3 \pm 8.3 \approx 120.3 \pm 5.9 and P > 0.05). The mean DBPs between the two groups were not statistically significant (78.6 \pm 4.4 \approx 79.3 ± 2.6 and P > 0.05) (Table 2). Conclusion: Ropivacaine is a newer ideal, comfortable safe anesthetic of choice for field block in inguinal hernia surgery cases, ASA I and II and by adding dexmedetomidine, we get a prolongation of analgesia when compared with bupivacaine and dexmedetomidine.

INTRODUCTION

Hernia is the word derived from Greek words "Herons" an offshoot or bulge. It is defined by Sir Astley Cooper (1804) as "protrusion of any viscus or part of the viscus through an abnormal opening in the walls of its containing cavity.^[1] The performed choice of anaesthesia for all adult inguinal hernia repair is local, it is safe, simple, effective, and economical, without anaesthetic side effects. Further

more local anaesthesia administered before the incision produces longer postoperative analgesia because local infiltration, theoretically inhibits build of local nociceptive molecules and therefore, there is better pain control in the postoperative period.^[2] Hernia repair can be performed under spinal, epidural, general and inguinal field block. Field block for inguinal hernia repair is the most costeffective anaesthetic technique for out patients undergoing unilateral inguinal herniorrhaphy with respect to speed of recovery.^[3] patient comfort and associated incremental costs. These are not provided into a satisfactory level by the commonly employed techniques, such as general anaesthesia (GA) or centrineuraxial blockade.^[4,5] Hence to meet the above requirements the present study of field block for inguinal hernia repair is undertaken.

Objectives

- To evaluate the advantages of this field block for inguinal hernia repair.
- To study the duration and quality of analgesia by using 0.5% bupivacaine and dexmedetomidine versus 0.375% ropivacaine and dexmedetomidine.
- To study effects of inguinal field block with respect to speed of recovery & patients comfort.
- Other side effects pertaining to the inguinal field block.

MATERIALS AND METHODS

This was a randomized, prospective comparative clinical study conducted in the Department of Anesthesiology

Inclusion Criteria

Age between 30 and 60 years and only male cases, American Society of Anesthesiologists (ASA I and II) cases, weight 40-65 kg, elective surgeries (inguinal hernioplasty).

Exclusion Criteria

Patient refusal, known allergy, coagulopathy, patient on β blockers, long-term analgesic therapy, drugs which are known to interact with study drugs.

Field block administration of drug mixture: Group 1 administered with 0.5% Bupivacaine and Dexmedetomidine and Group 2 administered with 0.375% Ropivacaine and Dexmedetomidine.

RESULTS

The two groups were matched in respect of their demographic characteristics such as age and weight. The baseline clinical variables such as ASA grade, pulse rate (PR), systolic blood pressure (SBP), diastolic blood pressure (DBP), sensory, and motor block were matched between the two groups (Table 1).

The two groups were not significantly differed in respect of their mean ages $(45.1 \pm 8.6 = 45.0 \pm 4.9)$. Similarly, they were also not significantly differed between the mean weights of two groups $(51.3 \pm 5.3 \approx 49.6 \pm 4.0 \text{ and } P > 0.05)$ (Table 1).

The baseline PR, SBP, and DBP were matched and shown in Table 3. The mean PRs between the two groups were not statistically significant ($86.9 \pm 8.9 \approx 84.5 \pm 9.3$ and P > 0.05). The mean SBPs between the two groups were not statistically significant ($121.3 \pm 8.3 \approx 120.3 \pm 5.9$ and P > 0.05). The mean DBPs between the two groups were not statistically significant ($78.6 \pm 4.4 \approx 79.3 \pm 2.6$ and P > 0.05) (Table 2).

Cable 1: Comparison of age between 2 groups Age in years	s N (%)		
	Group 1	Group 2	
30-39	20 (34.5)	10 (17.2)	
40-49	12 (20.7)	34 (58.6)	
50-59	26 (44.8)	14 (24.2)

Rescue analgesia	217.2±17.5	453.2±20.2	<0.0001

DISCUSSION

Field block is a simple, frequently used technique which provides very effective analgesia in lower abdominal surgeries. Ropivacaine is a newer drug with a more safety margin with reduced risk of cardiotoxicity. Dexmedetomidine is an $\alpha 2$ agonist which is very much used nowadays as an additive with local anesthetics. It gives intraoperative and post-operative analgesia.^[6] Moreover, it is devoid of opioid side effects but may produce sedation, bradycardia, and hypotension..^[7] In our study in Group 2 patients out of 29 patients 2 patients were developed bradycardia with hypotension, they required atropine and ephedrine. Al-Ghanem et al. have reported the use of dexmedetomidine to be associated with decrease in heart rate and blood pressure.^[6] No patients have developed any nausea or vomiting in both groups. But in Group 2, patients were free of anxiety and they were comfortable.^[8]

Both groups did not require any sedation intraoperatively. ^[9] Yaksh and Reddy studied that a powerful analgesia can be produced by selectively activating adrenergic, opiate, and baclofenergic receptor systems in the fieldcord.^[10]

CONCLUSION

Ropivacaine is a newer ideal, comfortable safe anesthetic of choice for field blocks in inguinal hernia surgery cases, ASA I and II and by adding dexmedetomidine, we get a prolongation of analgesia when compared with bupivacaine and dexmedetomidine.
